

[Code Outline]

- In this code according to the requirements, i used matplotlib to go about the data visualization, even if you want a more dynamic visualization implemented based on future needs that may arise, then i can always handle that with matplotlib and that is why i used it.
- The invoice when created auto generates a pdf, the pdf can be accessed from it's path and will be mailed to the customer at the begining of every new month.
- I have also added the creation views for each model like customer, assetpricing, invoice etc
- Celery was used for the scheduling

These few with many other sub features was added, and in order not to write abstractly, more perfection can be done upon the further request of the frontend developer.

the current template of account_dashboard is not fully styled, but is a good example of implementing each feature properly. You can look at the code, run and explore before merging.
